PREFACE

Alberta population projections for the period 1982-2011 were prepared by the Alberta Bureau of Statistics in co-operation with a sub-committee of the Statistics Coordinating Committee comprised of representatives from several Alberta government departments and agencies. Sub-committee members, through their knowledge of users' requirements and experience relevant to population projections, were able to provide considerable guidance in formulating the assumptions and developing the methodology upon which the projections are based. Although the sub-committee has been consulted throughout the project and its advice taken wherever possible, the Bureau of Statistics remains responsible for decisions between alternative approaches where advice was divided, and for implementing compromises where necessary. It is possible that while the projections reflect a consensus within the sub-committee, they may not correspond entirely with the policy or expectations of any one participating agency.

The assistance and co-operation of the following departments and agencies in making available personnel to contribute to the project through participation in the sub-committee are gratefully acknowledged:

Alberta Economic Development
Alberta Education
Alberta Environment
Alberta Hospitals and Medical Care
Alberta Manpower
Alberta Municipal Affairs
Alberta Social Services & Community Health
Alberta Solicitor General
Alberta Transportation
Energy Resources Conservation Board

Acknowledgement must also be extended to Professor Charles Hobart of the Department of Sociology, University of Alberta who has made invaluable contributions throughout the development of these projections. On the basis of sub-committee examination of all series, only three (Series 1, 5 & 9) were selected for publication of detailed information. The remaining series are available in print-out form on request. Please contact:

1.0 INTRODUCTION

The purpose of this publication is to provide Alberta population projections for the years 1982-2011 to policy planners and researchers within and outside the government. This publication provides a brief discussion on highlights from selected series and the assumptions used in the development of the projections. The population projections for Alberta 1982-2011 were prepared using a cohort survival model. The operation of the model starts with a base population tabulated by sex and single years of age. Births are added, deaths subtracted and net migration added to the appropriate sex and age category of the base population. The procedure is repeated for 30 successive years to yield population projections by sex and single years of age to the year 2011.

The 1981 Census population by age and sex for Alberta was used as input for the base population. Assumptions on fertility, mortality and migration were employed to project births, deaths and net migration for each year within the projection period. In total nine series of projections were produced from a combination of three fertility, three migration and one mortality assumptions. Total projected populations and the growth rates from all nine series are presented. Detailed age-sex breakdowns for Projection Series 1 (low fertility and low migration assumptions), Projection Series 5 (medium fertility and medium migration assumptions) and Projection Series 9 (high fertility and high migration assumptions) are provided in this publication. Similar details from the other projection series are available on request.

2.0 HIGHLIGHTS

Population growth rates for all nine projection series are lower than those experienced in the recent past. This is primarily a reflection of the lower migration levels which are assumed. In the early years these are assumed to be quite low, while increases in later years will result in migration ranging from 27,000 per year in the low case to 72,400 in the high case (Tables 5-7).

The population of Alberta is projected to grow from 2.24 million in 1981 to reach a range between 2.46 and 2.54 million by 1986 (Table 1 and Chart 1). Population growth during the 1981-86 period is projected to range from an average of 44,000 per year to 60,000 per year, a substantial decline from the comparable figure of 80,000 recorded during 1976-81.

By the year 2011, Alberta's population is expected to reach 3.54 million using the low fertility and low migration assumptions of Series 1. This represents an average annual growth rate of 1.5% over the 30 years. The medium fertility and migration assumptions (Series 5) result in a population of 4.19 million by 2011, an average growth rate of 2.1%. In the high growth scenario, population growth averages 2.9% annually, reaching a level of 5.27 million by 2011.

A general aging of the population is apparent in the various projection series, though there are some variations reflecting the fertility and migration assumptions of the various series (Charts 2-4). The percentage of children (aged 0-14) is expected to decline substantially from the 1981 figure of 24.3% to a range from 17.6% in the low growth case to 21.5% in the high growth case by 2011. The labour force population (persons aged 15-64) as a percentage of Alberta's population is expected to grow from 68.6% in 1981 to 72.8% in 2011 according to the low growth projection (Series 1) and 72.0% in the high growth situation (Series 9). In absolute numbers this group will grow from 1.53 million in 1981 to 2.58 million according to Series 1 and 3.80 million according to Series 9. The

percentage of persons aged 65+ is expected to grow from its 1981 level of 7.1% to 9.6% in the low case and decline to 6.5% in the high case.

The child dependency ratio (ratio of children 0-14 to the labour force population 15-64) would decline from its 1981 level of 35.4% to 32.9% in 1991 and 24.2% in 2011 according to the low projection (Series 1). In the high projection (Series 9), the ratio is expected to remain stable in the 1981-1991 period and then decline to 29.8% by 2011.

3.0 FERTILITY ASSUMPTIONS

Fertility in Alberta has declined continuously over the last few decades. Total fertility rates have declined from 4.27 (births per woman aged 15-49) in 1961 to 1.86 in 1981. This decline in fertility has affected all age groups among women of childbearing age. While fertility rates for women aged 45-49 have been insignificant, more than two thirds of births are now accounted for by mothers aged 20-29. Since labour force participation rates for women in this age group have climbed considerably, it is possible that fertility among women in this group will decline further in the future. Historical trends in birth statistics like number of children born to ever-married women and age specific fertility rates suggest the possibility of low fertility rates in the future. It is unlikely that high fertility rates as observed in the 50's and early 60's will be repeated. Anticipated changes in future fertility rates are expected to be slight. To allow for possible variations in future fertility rates three sets of fertility assumptions are used for the population projections (Table 2).

3.1 Low Assumption

Total fertility rates will continue to decline in Alberta at a rate of 2% annually which was the average rate of decline observed between 1972 to 1981. The total fertility rate is expected to decline to a level of 1.6 in 1989 and stabilize at that level until the end of the projection period.

3.2 Medium Assumption

Total fertility rates will remain at the 1981 level of 1.86 throughout the projection period.

3.3 High Assumption

Total fertility rates will increase slightly each year at the rate of 0.9%. The rate will reach the maximum of 2.04 children per woman aged 15-49 by 1991 and remain at that level until the end of the projection period.

4.0 MORTALITY ASSUMPTION

Alberta's mortality rate has declined steadily over the last few decades. The crude death rate for Alberta has declined from 8.4 per thousand in 1921 to 6.1 per thousand in 1980. From a record high death rate of 9.1 per thousand recorded in 1929, the provincial rate has displayed a general downward trend, though with some small year-to-year fluctuations. This improvement in mortality rates can be attributed to improvements in living conditions, health care and medical technology. By 1956 the provincial crude death rate had attained the level of 6.9 per thousand population, and by 1977, the provincial crude death rate had reached a low level of 6.1 per thousand. It has stabilized at that level during recent years. The crude death rates for both 1978 and 1980 were 6.1, while for 1979, the crude death rate was 6.0. It is likely that in the future, mortality will resemble this recent trend.

For projection purposes, the crude death rate is not a suitable parameter for projecting mortality because it does not reflect the age-sex composition of the population. The use of age-sex specific survival ratios, which provide the probabilities of surviving from one age group to the next, will generate more reliable results. The 1981 life table survival ratios were employed as the mortality assumption (Table 3). Given the stability of mortality rates in recent years (discussed in the above paragraph), it is assumed that the mortality level attained in 1981 will be maintained throughout the projection period.

5.0 MIGRATION ASSUMPTIONS

Migration assumptions for the projection period were prepared based on historical analysis of the associations between economic indicators and net migration to Alberta. Observations on the Alberta Gross Domestic Product (GDP), the ratio between the Alberta Gross Domestic Product (GDP) and the Canada Gross Domestic Product (GDP) and net migration rates of Alberta suggest that a positive relationship exists between economic activity and

[1] These figures indicate chances of survival of an individual at each age.

Prepared by: Alberta Bureau of Statistics

net migration. Four distinct periods have been identified. From 1961 to 1966 annual net migration rates averaged 0% when economic activity in Alberta can be characterized as slow. From 1966 to 1971 annual net migration rates averaged 1.0%. Average percent change in GDP was slightly higher during this period. From 1971 to 1976 average net migration was 1.3% and the Alberta economy was very active in preparation for the boom years ahead. The period 1976 to 1981 witnessed the continuation of high economic growth accompanied by an average annual net migration rate of 2.8%. An examination of the ratios of Alberta GDP relative to Canada GDP during the four periods reflect similar relationships with migration. The four average migration rates noted above were used as a basis for determining the different assumed migration levels during the projection period.

Historical data on migration show that net migration to Alberta had increased drastically since 1972, up to a level of 69,400 during 1980-81. However, recent migration estimates show that the high migration trend has stopped since the fourth quarter of 1981. Net migration has declined from 21,280 in the fourth quarter of 1981 to 10,840 in the first quarter of 1982. During the latter half of 1982, migration has declined significantly further. In the third quarter of 1982, net migration has declined to 5,625 and in the fourth quarter, to -500. This decline is mainly due to a decrease in interprovincial migration. It is likely that the new trend of low migration will extend into the near future. In formulating these migration assumptions, it is projected that net migration to Alberta will increase from the current levels. By 1997, migration is assumed to reach rates which correspond to those attained in each of three historical periods. After 1997 the volume of migration is assumed to be constant.

The net migration assumptions are composed of two components, interprovincial migration and international migration. Both are affected by economic and social conditions. Interprovincial migration is dynamic because of freedom of mobility in Canada. The volume of interprovincial migration is largely reflected in the final net migration figures. Immigration is tied to institutional factors. It is influenced by federal policy and by loca-

tional preferences of immigrants to come to Alberta. Emigration is determined by a host of social-economic factors, the effects of which cannot be readily measured. In Alberta the amount of emigration has been approximated using a multiplier approach. The number of emigrants is generally very small in comparison to immigration and interprovincial migration.

In preparing the assumptions the time lag of population movements in response to the economy has been taken into consideration. It is assumed that in a recession, people who had recently arrived from other provinces may take little time to decide to return if the situation affects them directly. A weak economy also discourages in-migration and immigration. On the other hand, when the economy improves, potential in-migrants from other provinces may take a wait and see position until they are assured that economic opportunities are strong and stable in Alberta before they move in. This may take from six months to a year. For immigrants, because of legal processing time, the lag may be an additional six to nine months.

The projected 1982-83 international migration of 12,000 was the five year average for the period 1976-81. Future international migration levels vary with the three asuumptions, taking into account the time lag and allowing for possible changes in institutional and economic factors.

Since estimates on the age-sex characteristics of in-migrants and out-migrants are not available, an attempt is made to estimate the age-sex structure of migrants. These were derived using a residual analysis of census survival ratios and life table survival ratios. They represent the age-sex composition of the balance of migrants to Alberta during the intercensal period 1976-81. The negative percentages in the older age groups indicate a loss through migration of persons in those age groups. Since the computer model does not require the age-sex breakdowns of in-migrants and out-migrants separately for input, the age-sex estimates of migrants for the 1976-81 period are used (Table 4). It is assumed that, during the projection period, Alberta will continue to gain younger persons and lose older persons through migration, and the age-sex structure of the remaining migrants will be similar to those during the period 1976-81.

[1] CSR: Census Survival Ratios; LTSR: Life-Table Survival Ratios.

5.1 Low Migration Assumption

The low migration assumption (Table 5) assumes that net migration will decline in 1982-83 to 3,000 (a migration rate of 0.1%) and will increase slowly to 10,000 (0.3%) by 1986-87. After 1987, net migration will increase by 1,600 a year until 1996-97, reaching a level of 27,000. It is assumed that in 1996-97 the net migration rate will reach approximately 1.0% which was the average rate recorded for the period 1966-71. After 1997, net migration is assumed to be constant at 27,000 annually.

5.2 Medium Migration Assumption

The medium migration assumption (Table 6) assumes that net migration will decline in 1982-83 to 7,000 (a migration rate of 0.3%) and will stay at that level in 1983-84. Net migration will increase to 11,000 (0.5%) in 1984-85. A significant increase will occur in 1986-87 to 20,000 (0.8%). From 1988 to 1997 net migration will increase by 2,000 a year to 42,000. The net migration rate reached in 1996-97 (1.3%) will be similar to the average migration rate for the 1971-76 period. After 1997, net migration is assumed to be constant at 42,000 annually.

5.3 High Migration Assumption

The high migration assumption (Table 7) assumes that net migration will decline to 14,000 (a migration rate of 0.6%) in 1982-83, and increase slightly to 16,000 (0.7%) in 1983-84. A significant increase will occur in 1984-85 to 26,000 (1.0%), mainly due to an increase in interprovincial migration. After 1987, net migration is expected to increase annually by 3,700, mainly through interprovincial migration, to a level of 72,400 by 1996-97. The rate of migration is assumed to be 2.1%, which is approximately mid-way between the average net migration rate of 1.3% for 1971-76 and 2.8% for 1976-81. This is an optimistic assumption based on a return to solid growth of the Alberta

economy by the mid 80's. However, since it is unlikely that there will be a return of the relative magnitude of development associated with the resource boom of 1976-81 period, average migration rates reaching the 2.8% level achieved in this earlier period are not expected to recur. However, in terms of volumes, the 72,400 will be more than what Alberta has gained in net migration (69,400) during 1980-81, the peak migration year. Annual net migration after 1997 is assumed to be constant at 72,400.

6.0 POPULATION PROJECTION TABLES

This section presents the results of the population projections for Alberta, 1982-2011. The projected total population and projected growth rates from the nine series of the projections are presented in Tables 8 and 9 respectively. Age-sex pyramids for the three selected series - Series 1, 5 and 9 - showing the age-sex structure of the Alberta population in 1981, 1991, 2001 and 2011 are presented in Charts 2 to 4. Projected population by broad age groups for Series 1, 5 and 9 are presented in Tables 10 to 12. Detailed age-sex breakdowns for Projection Series 1, 5 and 9 are presented in Tables 13 to 18. The assumptions used in the projection series are as follows.

ASSUMPTIONS USED IN THE PROJECTION SERIES

Series 1	Low Migration, Low Fertility
Series 2	Low Migration, Medium Fertility
Series 3	Low Migration, High Fertility
Series 4	Medium Migration, Low Fertility
Series 5	Medium Migration, Medium Fertility
Series 6	Medium Migration, High Fertility
Series 7	High Migration, Low Fertility
Series 8	High Migration, Medium Fertility
Series 9	High Migration, High Fertility

GLOSSARY

age-specific fertility rate - the number of births per 1,000 women of a specific age group within the child bearing age range (age 15-49).

child dependency ratio - the ratio of children under 15 to persons between the ages of 15 and 64.

cohort - a group of persons born in a specified year or period.

death rate, or crude death rate - the number of deaths in a year divided by the total population.

emigration - the migration of population out of a country.

fertility - the contribution of births to population change.

gross domestic product (GDP) - the value of total production of goods and services in a given geographical area for a specific time period.

immigration - the migration of population into a country.

in-migration - the migration of population into a geographical unit within the country.

labour force participation rate - the proportion of the working age population in the labour force.

life table - a table of statistics showing the probability of death at each age, the probability of survival to the next age, and other related mortality indicators for a stated population.

life table survival ratios - ratios calculated from the life table, representing the probability of survival from one age group to another.

GLOSSARY (CONT'D)

migration - a permanent change of residence from one geographical unit to another.

mortality - the contribution of deaths to population change.

net migration - the difference between in-migration (including immigration) and out-migration (including emigration) for a geographical unit.

old age dependency ratio - the ratio of persons aged 65 years and over to persons between the ages of 15 and 64.

out-migration - the migration of population out of a geographical unit within the country.

population growth rate - population growth occurring in a certain period/year divided by the base population at the beginning of that period/year.

projection - a figure for a future date derived from carrying forward assumed trends, which are specifically defined.

total fertility rate - the sum total of age-specific fertility rates.
